#### Penrose tilings

The union of which defines (up to multiplicity) a complete tiling.

Introductory example

### A generic result

We here provide a general way to find such tricky tiles.

Formally, we constructively prove:

Theorem (Fernique & Ollinger, 2010)

The limit set of a good combinatorial substitution is sofic.

Extends and (hopefully) simplifies previous similar results:

- Shahar Mozes (1990);
- Chaim Goodman-Strauss (1998).

### Sofic tilings

Decorated tiles and tilings:

- A decorated tile is a polytope of  $\mathbb{R}^d$  with finitely many *facets*, on which is defined a real map, called *decoration*;
- Two decorated tiles match if their intersection (if any) is made of entire faces on which decorations are equal;
- A decorated tiling is a covering of D ⊂ ℝ<sup>d</sup> by pairwise matching decorated tiles. It is complete if D = ℝ<sup>d</sup>;
- Decorated tile set  $\tau$  (+direct isometries)  $\rightsquigarrow$  decorated tilings  $\Lambda_{\tau}$ .

### Sofic tilings

Decorated tiles and tilings:

- A decorated tile is a polytope of  $\mathbb{R}^d$  with finitely many *facets*, on which is defined a real map, called *decoration*;
- Two decorated tiles match if their intersection (if any) is made of entire faces on which decorations are equal;
- A decorated tiling is a covering of D ⊂ ℝ<sup>d</sup> by pairwise matching decorated tiles. It is complete if D = ℝ<sup>d</sup>;
- Decorated tile set  $\tau$  (+direct isometries)  $\rightsquigarrow$  decorated tilings  $\Lambda_{\tau}$ .

Tiles and tilings: by removing decorations (map  $\pi$ ).

### Sofic tilings

Decorated tiles and tilings:

- A decorated tile is a polytope of  $\mathbb{R}^d$  with finitely many *facets*, on which is defined a real map, called *decoration*;
- Two decorated tiles match if their intersection (if any) is made of entire faces on which decorations are equal;
- A decorated tiling is a covering of D ⊂ ℝ<sup>d</sup> by pairwise matching decorated tiles. It is complete if D = ℝ<sup>d</sup>;
- Decorated tile set  $\tau$  (+direct isometries)  $\rightsquigarrow$  decorated tilings  $\Lambda_{\tau}$ .

Tiles and tilings: by removing decorations (map  $\pi$ ).

#### Definition (Sofic tiling)

A set of tilings is sofic if it is the image under  $\pi$  of some set  $\Lambda_{\tau}$ , with  $\tau$  being <u>finite</u> (up to direct isometries).

### Combinatorial substitutions

We are inspired by Natalie Priebe-Frank:

#### Definition (Combinatorial substitution)

A combinatorial substitution is a finite set of rules  $(P, Q, \gamma)$ , where P is a tile, Q is a finite connected tiling, and  $\gamma : \partial P \to \partial Q$  maps distinct facets on disjoint sets of facets.

The tiling Q is a macro-tile. If f is the k-th facet of P, then  $\gamma(f)$  is the k-th macro-facet of Q.

### Combinatorial substitutions

Two macro-tiles match if their intersection contains only entire macro-facets; a macro-tiling is a tiling whose tiles can be partitioned into matching macro-tiles.

Given a combinatorial substitution  $\sigma = \{(P_i, Q_i, \gamma_i)_i\}$ :

#### Definition (Preimage)

A tiling T by  $P_i$ 's is the  $\sigma$ -preimage of a macro-tiling T' by  $Q_i$ 's if there is a one-to-one correspondence between the tiles of T and the macro-tiles of T' which preserves the combinatorial structure.

#### Definition (Limit set)

The limit set of  $\sigma$ , denoted by  $\Lambda_{\sigma}$ , is the set of complete tilings which admit an infinite sequence of  $\sigma$ -preimages.

### Good combinatorial substitutions

A good combinatorial substitution is consistent and connecting:

#### Definition (Consistency)

A combinatorial substitution  $\sigma = \{(P_i, Q_i, \gamma_i)_i\}$  is consistent if any complete macro-tiling by  $Q_i$ 's admits a  $\sigma$ -preimage.

#### Definition (Connectivity)

A combinatorial substitution  $\sigma = \{(P_i, Q_i, \gamma_i)_i\}$  is connecting if the dual graph of any  $Q_i$  has a subgraph  $N_i$ , called its network, s.t.

- $N_i$  is a star connecting macro-facets through ports;
- 2 removing  $N_i$ -edges yields a graph connecting macro-facets;
- **③** the center of  $N_i$ , called central tile, is in the interior of  $Q_i$ ;

### Self-simulation

Let  $\sigma = \{(P_i, Q_i, \gamma_i)_i\}$  be a combinatorial substitution.

#### Definition (Self-simulation)

A decorated tile set  $\tau$  self-simulates for  $\sigma$  if there are  $\tau$ -tilings, called  $\tau$ -macro-tiles, and a map  $\phi$  from those to  $\tau$ , such that

- $\forall \tau$ -macro-tile Q,  $\exists i$  t.q.  $\pi(Q) = Q_i$  and  $\pi(\phi(Q)) = P_i$ ;
- 2 any complete  $\tau$ -tiling is also a  $\tau$ -macro-tiling;
- **3** any  $\tau$ -macro-tile Q is combinatorially equivalent to  $\phi(Q)$ .

### Self-simulation

Let  $\sigma = \{(P_i, Q_i, \gamma_i)_i\}$  be a combinatorial substitution.

#### Definition (Self-simulation)

A decorated tile set  $\tau$  self-simulates for  $\sigma$  if there are  $\tau$ -tilings, called  $\tau$ -macro-tiles, and a map  $\phi$  from those to  $\tau$ , such that

- $\forall \tau$ -macro-tile Q,  $\exists i$  t.q.  $\pi(Q) = Q_i$  and  $\pi(\phi(Q)) = P_i$ ;
- 2 any complete  $\tau$ -tiling is also a  $\tau$ -macro-tiling;
- **3** any  $\tau$ -macro-tile Q is combinatorially equivalent to  $\phi(Q)$ .

#### Proposition

If  $\sigma$  is consistent and  $\tau$  self-simulates for  $\sigma$ , then  $\pi(\Lambda_{\tau}) \subset \Lambda_{\sigma}$ .

Introductory example

2 General case

Introductory example 000000	General case 000000	Constructive

Settings

proof

Let  $\sigma = \{(P_i, Q_i, \gamma_i)_i\}$  be a good combinatorial substitution. Tiles and internal facets of the  $Q_i$ 's:  $(T_i)_{1 \le i \le n}$  and  $(f_j)_{1 \le j \le m}$ .  $N_{\sigma}(i, k)$  denotes the index of the *k*-th facet of  $T_i$  if it is internal, or a special value "port", "macro-facet" or "boundary" otherwise.

Settings

Let  $\sigma = \{(P_i, Q_i, \gamma_i)_i\}$  be a good combinatorial substitution. Tiles and internal facets of the  $Q_i$ 's:  $(T_i)_{1 \le i \le n}$  and  $(f_j)_{1 \le j \le m}$ .  $N_{\sigma}(i, k)$  denotes the index of the k-th facet of  $T_i$  if it is internal, or a special value "port", "macro-facet" or "boundary" otherwise.

 $\tau$ -tiles will be decorated  $T_i$ 's. On each facet will be encoded:

- a facet-index (or special value), called macro-index;
- a tile-index (or 0), called parent-index;
- a facet-index (or special value), called neighbor-index. Clearly,  $\tau$  is necessarily finite (but possibly huge).

Steps 1–3 of 5

We define  $\tau$  step by step by allowing/forbidding indices on facets.

Step 1 specifies all the macro-indices:

**1** macro-index of the *k*-th facet of a decorated  $T_j$ :  $N_{\sigma}(j, k)$ .

Steps 1–3 of 5

We define  $\tau$  step by step by allowing/forbidding indices on facets.

Step 1 specifies all the macro-indices:

**1** macro-index of the *k*-th facet of a decorated  $T_i$ :  $N_{\sigma}(j, k)$ .

Steps 2–3 specify non-port facets crossed by no network:

- **②** parent-index of such a facet in a  $Q_i$ : 0 if external, any j with  $T_j = P_i$  otherwise, with uniform indices within each  $\tau$ -tile;
- neighbor-index of such a facet in a k-th macro-facet: N<sub>σ</sub>(j, k), where j is the parent-index within the corresponding τ-tile; neighbor-index of other such facets: copy of the macro-index.

▲ロト ▲帰ト ▲ヨト ▲ヨト - ヨ - の々ぐ

### Steps 4–5 of 5

Steps 4–5 specify parent/neighbor pairs on networks and ports:

 on the k-th branch (strictly) and k-th port of a macro-tile: any pair not forbidden on the k-th facet of its parent-tile, with uniform pairs within each τ-tile;

### Steps 4–5 of 5

Steps 4–5 specify parent/neighbor pairs on networks and ports:

- on the k-th branch (strictly) and k-th port of a macro-tile: any pair not forbidden on the k-th facet of its parent-tile, with uniform pairs within each τ-tile;
- on the facets of a <u>central</u> τ-tile T: copy all the pairs of any non-central decorated tile which has as many facets as T (one says that T derives from this non-central decorated tile).

### Steps 4–5 of 5

Steps 4–5 specify parent/neighbor pairs on networks and ports:

- on the k-th branch (strictly) and k-th port of a macro-tile: any pair not forbidden on the k-th facet of its parent-tile, with uniform pairs within each τ-tile;
- on the facets of a <u>central</u> τ-tile T: copy all the pairs of any non-central decorated tile which has as many facets as T (one says that T derives from this non-central decorated tile).

This completly defines the decorated tile set  $\tau$ .

▲ロト ▲帰ト ▲ヨト ▲ヨト - ヨ - の々ぐ

# First inclusion: $\pi(\Lambda_{\tau}) \subset \Lambda_{\sigma}$

Let Q be a  $\tau$ -macro-tile with parent-index j and central  $\tau$ -tile  $\mathcal{T}'$ . We define  $\phi(Q)$  as the tile  $T_j$  endowed with the decorations of  $\mathcal{T}'$ . This easily yields that  $\tau$  self-simulates for  $\sigma$ , whence  $\pi(\Lambda_{\tau}) \subset \Lambda_{\sigma}$ . General case

# First inclusion: $\pi(\Lambda_{\tau}) \subset \Lambda_{\sigma}$

Let Q be a  $\tau$ -macro-tile with parent-index j and central  $\tau$ -tile T'. We define  $\phi(Q)$  as the tile  $T_j$  endowed with the decorations of T'. This easily yields that  $\tau$  self-simulates for  $\sigma$ , whence  $\pi(\Lambda_{\tau}) \subset \Lambda_{\sigma}$ .

Provided that  $\phi(\mathcal{Q}) \in \tau$  holds!

# First inclusion: $\pi(\Lambda_{\tau}) \subset \Lambda_{\sigma}$

Let  $\mathcal{Q}$  be a  $\tau$ -macro-tile with parent-index j and central  $\tau$ -tile  $\mathcal{T}'$ . We define  $\phi(\mathcal{Q})$  as the tile  $\mathcal{T}_j$  endowed with the decorations of  $\mathcal{T}'$ . This easily yields that  $\tau$  self-simulates for  $\sigma$ , whence  $\pi(\Lambda_{\tau}) \subset \Lambda_{\sigma}$ .

Provided that  $\phi(\mathcal{Q}) \in \tau$  holds!

Let  $\mathcal{T}$  be the non-central  $\tau$ -tile from which derives  $\mathcal{T}'$  (step 5):

- if  $T_j$  is central, then  $\phi(Q)$  also derives from T;
- otherwise, neighbor-indices of *T*-facets crossed by no network are copies of macro-indices allowed only on a decorated *T<sub>j</sub>*. This yields π(*T*) = *T<sub>j</sub>*, and thus φ(*Q*) = *T*.

General case

### Converse inclusion: $\Lambda_{\sigma} \subset \pi(\Lambda_{\tau})$

#### Let $P_0 \in \Lambda_{\sigma}$ and, for any $n \ge 1$ , $P_n$ be a preimage of $P_{n-1}$ .

### Converse inclusion: $\Lambda_{\sigma} \subset \pi(\Lambda_{\tau})$

Let  $P_0 \in \Lambda_{\sigma}$  and, for any  $n \ge 1$ ,  $P_n$  be a preimage of  $P_{n-1}$ .

Let  $\tau'$  extend  $\tau$  by allowing a decoration "undefined" on facets. We fix *n* and inductively define  $\tau'$ -tiling  $(\mathcal{P}_k)_{n \geq k \geq 0}$  as follows:

- $\mathcal{P}_n$ : endow uniformly  $\mathcal{P}_n$  with "undefined" decorations;
- *P*<sub>k-1</sub>: endow each macro-tile of *P*<sub>k-1</sub> as in steps 1–3 and copy decorations of the corresponding τ'-tile of *P*<sub>k</sub> on its network.

The "undefined" decorations appear in the  $\mathcal{P}_k$ 's on sort of grids whose cells grow when k decreases.

### Converse inclusion: $\Lambda_{\sigma} \subset \pi(\Lambda_{\tau})$

Let  $P_0 \in \Lambda_{\sigma}$  and, for any  $n \ge 1$ ,  $P_n$  be a preimage of  $P_{n-1}$ .

Let  $\tau'$  extend  $\tau$  by allowing a decoration "undefined" on facets. We fix *n* and inductively define  $\tau'$ -tiling  $(\mathcal{P}_k)_{n \ge k \ge 0}$  as follows:

- $\mathcal{P}_n$ : endow uniformly  $\mathcal{P}_n$  with "undefined" decorations;
- *P*<sub>k-1</sub>: endow each macro-tile of *P*<sub>k-1</sub> as in steps 1–3 and copy decorations of the corresponding τ'-tile of *P*<sub>k</sub> on its network.

The "undefined" decorations appear in the  $\mathcal{P}_k$ 's on sort of grids whose cells grow when k decreases.

Taking  $n \to \infty$  yields a  $\tau'$ -tiling  $\mathcal{P}_0$  whose "undefined" decorations appear only on a star or a line – easily tranformed into a  $\tau$ -tiling. This yields  $P_0 = \pi(\mathcal{P}_0) \in \pi(\Lambda_{\tau})$ , and thus  $\Lambda_{\sigma} \subset \pi(\Lambda_{\tau})$ .

# Bringing all together

Given any good combinatorial substitution  $\sigma,$  we are thus able to defined a finite decorated tile set  $\tau$  such that

$$\Lambda_{\sigma} = \pi(\Lambda_{\tau}).$$

This yields the claimed result:

Theorem (Fernique & Ollinger, 2010)

The limit set of a good combinatorial substitution is sofic.

# Bringing all together

Given any good combinatorial substitution  $\sigma,$  we are thus able to defined a finite decorated tile set  $\tau$  such that

$$\Lambda_{\sigma} = \pi(\Lambda_{\tau}).$$

This yields the claimed result:

Theorem (Fernique & Ollinger, 2010)

The limit set of a good combinatorial substitution is sofic.

Unfortunately  $\tau$  is rather huge (up to millions of tiles!). Can we achieve a much lighter generic construction?

# Thank you for your attention
